ABNORMAL SEMEN PH

Acidic Ejaculate, Acidic Semen, Alkaline Ejaculate, Alkaline Smen, Low Ph Of Ejaculate, High Ph Of Ejaculate

A pH value outside of the normal range which is harmful to sperm.

♀ Symptom ♂ Male

About Abnormal semen pH

A normal pH of human semen range of 7.1-8.0, which is higher than the neutral pH. Pure water is neutral, at pH 7, being neither an acid nor a base. Solutions with a pH less than 7 are acidic and solutions with a pH greater than 7 are basic.

Mature sperm cells in the testes that are ready for ejaculation pass through the epididymis where prostate fluid, which is rich in proteins and other factors such as citric acid and zinc, is added. Semen is further augmented by fluid from the seminal vesicles, which are responsible for establishing the alkaline pH of semen. About 50 - 70% of seminal fluid in humans originates from the seminal vesicles, but is not expelled in the first ejaculate fractions which are dominated by spermatozoa and prostatic fluid. Alkaline pH of semen helps neutralize the acidity of the vaginal tract, prolonging the lifespan of sperm.

Abnormal semen pH as a symptom is associated with several conditions such as infection of genitourinary tract, hypospermia or obstructive azoospermia.

A genitourinary infection

A basic ejaculate (higher pH value) may indicate an infection. When the male genitourinary tract is infected, bacteriotoxin, leukocytes, oxidative stress, and inflammatory factors may change the seminal plasma environment, which
leads to the impairment of sperm motility. Sperm motility is essential for fertilization. Progressive motility is a vital functional characteristic of sperm, and it measures the ability of sperm to penetrate into an egg, and migrate through cervical mucus.

**Hypospermia**

Hypospermia which means that a man has an unusually low ejaculate (or semen) volume, less than 1.5 ml can sometimes be associated with semen pH more than 7.8. This can indicate some hypothalamic disorder which has to be treated. In cases that the hypospermia is associated with pH less than 7.4, physician have to evaluate if there is not an absence of seminal vesicles.

**Obstructive azospermia**

Obstructive azoospermia (OA) is defined as the absence of sperms in the ejaculate. It is a common cause of male infertility and can result from infection, congenital anomalies, or iatrogenic (induced inadvertently by a physician or surgeon) injury. Acidic ejaculate (lower pH value) may indicate one or both of the seminal vesicles are blocked. The finding of acidic ejaculate helps physicians to determine the exact cause of infertility and solve the problem by removal of the obstruction.

**Prognosis**

Semen pH has little direct significance to sperm fertility potential. It is essential for protect of sperm from the environment in vagina. Also, the chemical environment of semen can have a profound effect on sperm quality, such as motility. Since pH affects the metabolic rate and the motility of sperm, it consequently alters the vitality of sperm.

In vitro, external pH is an important factor in the regulation of sperm physiology. An acid pH contributes to maintain a non-capacitated state preventing premature acrosomal reaction that event of the utmost importance for the development of mammalian fertilisation.

**Diagnoses**
Hypospermia
A condition in which a man has an unusually low ejaculate (or semen) volume.
