CLITOROMEGALY

Enlargement Of Clitoris, Macroclitoris, Cmg

An abnormally enlarged clitoris.

🛡️ Symptom  ⚭ Male & Female

About Clitoromegaly

Clitoromegaly (or macroclitoris) is an abnormal enlargement of the clitoris that is mostly congenital or acquired, though deliberately induced clitoris enlargement as a form of female genital body modification is achieved through various uses of anabolic steroids, including testosterone, and may also be referred to as clitoromegaly. Clitoromegaly is not the same as normal enlargement of the clitoris seen during sexual arousal.

The typical clitoris is defined as having a crosswise width of 3 to 4 mm (0.12 - 0.16 inches) and a lengthwise width of 4 to 5 mm (0.16 - 0.20 inches). On the other hand, in Obstetrics and Gynecology medical literature, a frequent definition of clitoromegaly is when there is a clitoral index (product of lengthwise and crosswise widths) of greater than 35 mm² (0.05 inches), which is almost twice the size given above for an average sized clitoral hood.

Clitoromegaly is a rare condition and can be either present by birth or acquired later in life. If present at birth, congenital adrenal hyperplasia can be one of the causes, since in this condition the adrenal gland of the female fetus produces additional androgens and the newborn baby has ambiguous genitalia which are not clearly male or female. In pregnant women who received norethisterone during pregnancy, masculinization of the fetus occurs, resulting in hypertrophy of the clitoris; however, this is rarely seen nowadays due to use of safer progestogens. It can also be caused by the autosomal recessive congenital disorder known as Fraser syndrome (a rare disorder that affects development starting before birth).

In acquired clitoromegaly, the main cause is endocrine hormonal imbalance affecting the adult woman, including polycystic ovarian syndrome (PCOS) and hyperthecosis. Acquired clitoromegaly may also be caused by pathologies affecting the ovaries and other endocrine glands. These pathologies may include virulent (such as arrenoblastoma) and neurofibromatosic tumors. Another cause is clitoral cysts. Sometimes there may be no obvious clinical or hormonal reason.

Female bodybuilders and athletes who use androgens, primarily to enhance muscular growth, strength and appearance, may also experience clearly evident enlargement of the clitoris and increases in libido. Women who use testosterone for therapeutic reasons (treating low libido, averting osteoporosis, as part of an anti-depressant regimen, etc.) experience some enlargement of the clitoris, although the dosages warranted for these conditions are much lower.

Early surgical reduction of clitoromegaly via full or partial clitoridectomy is controversial, and intersex women exposed to such treatment have spoken of their loss of physical sensation, and loss of autonomy. In recent years, human rights institutions have criticized early surgical management of such characteristics.
